# Outline

1. **Introduction**
2. Content-based models
3. Collaborative filtering
4. Latent factor models
5. Summary

# Recommender Systems

- Class of applications that predict user responses to options.
- **Non-personalized recommendations:**
  - *Editorial and hand-curated:* List of favorites, essential items, ...
  - *Simple aggregates:* Top 10, most popular, recent uploads, ...
- **Personalized recommendations:**
  - *Tailored to individual users:* Amazon, Netflix, YouTube, ...

# Recommender Systems: Examples

# Personalized Recommender Systems

- Two groups of recommender systems:
  - **Content-based:** Focus on the profiles (or features) of users/items.
  - **Collaborative filtering:** Focus on the interactions between users/items.
  - **Hybrid:** Use both content-based and interaction-based information.

# Utility Matrix

- We consider two classes of entities: **Users** and **items**.
- **Utility matrix** shows the preference of users for items.
  - The values come from an ordered set, e.g., 1-5 stars.
  - Assumed to be sparse, i.e., most entries are unknown.

	HP1	HP2	HP3	TW	SW1	SW2	SW3
<i>A</i>	4			5	1		
<i>B</i>	5	5	4				
<i>C</i>				2	4	5	
<i>D</i>		3					3

# Gathering Ratings

- **Explicit feedback:** Ask users to rate items.
  - E.g., YouTube asks for likes/dislikes of watched videos.
  - Users are generally unwilling to provide responses.
  - *Biased* as it comes from people willing to provide ratings.
- **Implicit feedback:** Learn ratings from user actions.
  - If a user watches a movie, the user is said to “like” it.
  - Hard to model low ratings: 0 (no rating) or 1 (like).

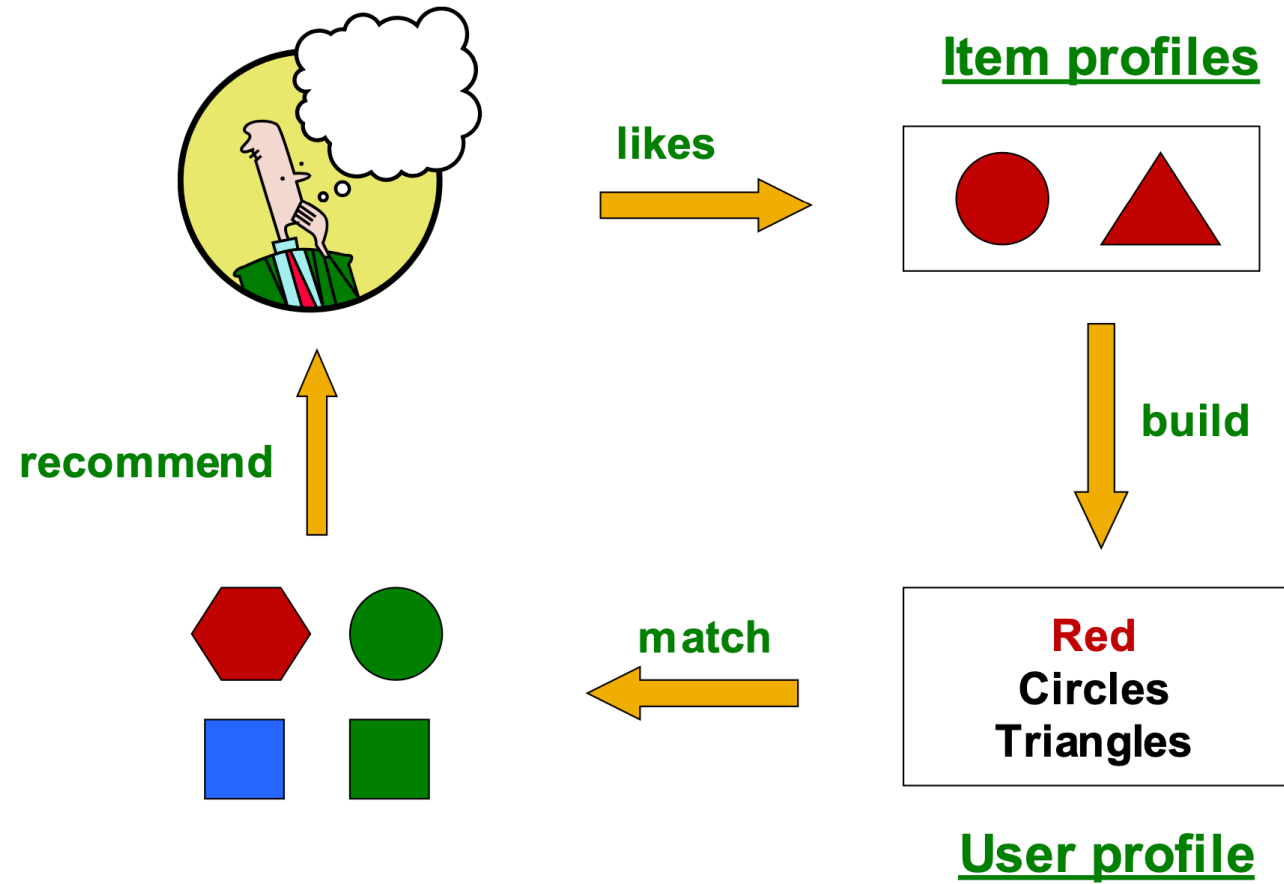

# Outline

1. Introduction
2. **Content-based models**
3. Collaborative filtering
4. Latent factor models
5. Summary

# Content-based Recommendation

- **Main idea:** Use the profiles of items.
  - E.g., for a movie, { genre, director, actors, plot, release year }
  - Recommend items similar to previous highly-rated items.
- **Examples:**
  - Recommend movies with same actor(s), director, genre, ...
  - Recommend websites or blogs with “similar” content.

# Plan of Action

Source: Stanford CS246 (2022)

# Item Profiles

- For each item, we create an **item profile** as a set of features.
- Recently, deep learning is used to find a good item profile.
  - E.g., a CNN is used to create latent information of item images.
- **Method 1:** Use pre-trained models.
- **Method 2:** Train an extractor in an end-to-end way.
  - Minimizing a recommendation loss.

*Common stop words*

*Less frequent terms with small TF-IDF*

*More frequent terms with higher TF-IDF*

auto repair

# Content-based: Pros and Cons

- **Pros:**

- No need for data on other users.
- Able to recommend items to users with unique tastes.
- Able to recommend new or unpopular items.
- Able to provide explanations (by listing content features).

- **Cons:**

- Finding the appropriate features may be difficult.
- New users may not have a profile.
- **Overspecialization:** Cannot recommend beyond user's profile.

# Outline

1. Introduction
2. Content-based models
3. **Collaborative filtering**
4. Latent factor models
5. Summary

# Collaborative Filtering

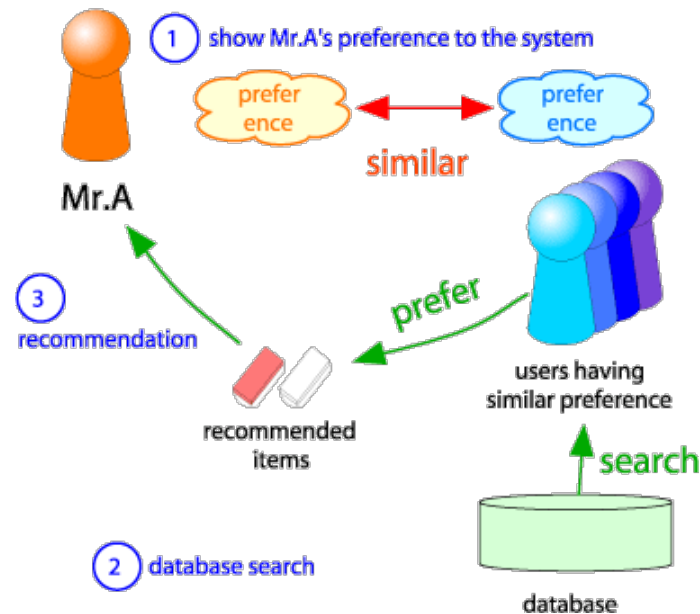

- **Collaborative filtering** focuses on the interactions, not contents.
  - Does not build item profiles or user profiles.
  - Uses rows/columns of the utility matrix as profile vectors.
- Comes in two flavors:
  - User-user collaborative filtering.
  - Item-item collaborative filtering.

# User-User Collaborative Filtering

- Given a user  $U$ , find users whose ratings are similar to  $U$ 's ratings.
- Estimate  $U$ 's ratings based on the similar users.

# Finding Similar Users

- There are various ways for defining which users are “similar.”
- **Jaccard similarity:**
  - Treat ratings as sets, ignoring the values (i.e., likes vs. dislikes).
  - For this example, it seems intuitively wrong.
    - Since  $\text{Jaccard}(A, B) = 1/5 < \text{Jaccard}(A, C) = 2/4$ . Does it make sense?

	HP1	HP2	HP3	TW	SW1	SW2	SW3
<i>A</i>	4			5	1		
<i>B</i>	5	5	4				
<i>C</i>				2	4	5	
<i>D</i>		3					3

# Finding Similar Users

- There are various ways for defining which users are “similar.”
- **Cosine similarity:**
  - Treat ratings as points (or vectors), considering blanks as 0.
  - Questionable, since *no rating* doesn't mean *dislike*.
  - In this example,  $v_A^T v_B / \|v_A\| \|v_B\| = 0.380$  and  $v_A^T v_C / \|v_A\| \|v_C\| = 0.322$ .

	HP1	HP2	HP3	TW	SW1	SW2	SW3
<i>A</i>	4			5	1		
<i>B</i>	5	5	4				
<i>C</i>				2	4	5	
<i>D</i>		3					3

# Rating Predictions

- **From similarity metrics to recommendations:**

- Let  $r_x$  be the vector of user  $x$ 's ratings.
- Let  $N$  be the set of  $k$  users most similar to user  $x$ .
- Let  $N' \subseteq N$  be the subset of users who rated item  $i$ .

- Prediction for item  $i$  of user  $x$ :

- **Simple version:**  $r_{xi} = \frac{1}{k'} \sum_{y \in N'} r_{yi}$ .
- **Complex version:**  $r_{xi} = \frac{\sum_{y \in N'} \text{sim}(x,y) \cdot r_{yi}}{\sum_{y \in N'} \text{sim}(x,y)}$ .

# Item-Item Collaborative Filtering

- **Another view: Item-item collaborative filtering.**
  - For item  $i$ , find other similar items.
  - Estimate rating for item  $i$  based on ratings for similar items.
  - Can use the same similarity metrics as in the user-user model.

$$r_{xi} = \frac{\sum_{j \in N(i;x)} \text{sim}(i, j) \cdot r_{xj}}{\sum_{j \in N(i;x)} \text{sim}(i, j)}$$

- $N(i; x)$  is the set of items similar to item  $i$  and rated by user  $x$ .

# Item-Item vs. User-User

- **Item-item similarity is often more reliable.**
  - Intuitively, items are classifiable in simple terms, e.g., one genre.
  - Users may like multiple genres, so harder to compute similarity.
- However, there is no clear advantage of one from another.
  - E.g., user-user is better for relatively new items.

	HP1	HP2	HP3	TW	SW1	SW2	SW3
<i>A</i>	4			5	1		
<i>B</i>	5	5	4				
<i>C</i>				2	4	5	
<i>D</i>		3					3

# Collaborative Filtering: Pros and Cons

- **Pros:**

- Do not have to come up with features (or profiles).

- **Cons:**

- Need enough users in the system to find a match.
- Cannot recommend new or unpopular items that have not been rated.
- Cannot recommend items to someone with unique taste.
  - I.e., tends to recommend popular items.

# Hybrid Approach

- Advanced recommender systems are **hybrid** and **multi-modal**.
  - **Hybrid**: Use both content and interaction information.
  - **Multi-modal**: Use different data modalities at the same time.
    - Textual reviews from users.
    - Image description of items.
    - Graph-structured interactions between users and items.
- There is no fixed way in deep learning.
  - Since different components can be combined in an end-to-end way.

# Outline

1. Introduction
2. Content-based models
3. Collaborative filtering
4. **Latent factor models**
5. Summary

# Latent Factor Models

- **Latent factor models** assume that:
  - There are **latent factors** that can represent users and items well.
  - Such latent factors can be extracted from the utility matrix.
- Many people consider latent factor models as a part of CF.
  - Since they share the same philosophy.
  - CF uses the rows and columns of  $R$  without modification.
  - Latent factor models extract (better) latent factors from  $R$ .

# Latent Factor Models

- **Idea:** Consider a utility matrix as the product of **factor matrices**.
  - E.g., users react to certain genres, famous actors, or directors.
- **UV decomposition** decomposes a utility matrix into  $U$  and  $V$ .
  - Each user and movie is summarized as a low-dimensional vector.

# UV Decomposition

- **Given** an  $m \times n$  utility matrix  $R$  (i.e.,  $m$  users and  $n$  items).
- **Find** an  $m \times k$  matrix  $U$  and  $n \times k$  matrix  $V$  such that:
  - $UV^T$  closely approximates  $R$  for the **non-blank entries**.
- **Use** the elements of  $UV^T$  to estimate the blank entries in  $R$ .
  - Compute  $\hat{r}_{xi} = u_x^T v_i$  to predict  $r_{xi}$ .

$$\begin{bmatrix} 5 & 2 & 4 & 4 & 3 \\ 3 & 1 & 2 & 4 & 1 \\ 2 & & 3 & 1 & 4 \\ 2 & 5 & 4 & 3 & 5 \\ 4 & 4 & 5 & 4 & \end{bmatrix} = \begin{bmatrix} u_{11} & u_{12} \\ u_{21} & u_{22} \\ u_{31} & u_{32} \\ u_{41} & u_{42} \\ u_{51} & u_{52} \end{bmatrix} \times \begin{bmatrix} v_{11} & v_{12} & v_{13} & v_{14} & v_{15} \\ v_{21} & v_{22} & v_{23} & v_{24} & v_{25} \end{bmatrix}$$

$R \qquad \qquad U \qquad \qquad V^T$

# Error Function

- **Root-mean-square error (RMSE)** measures the difference.

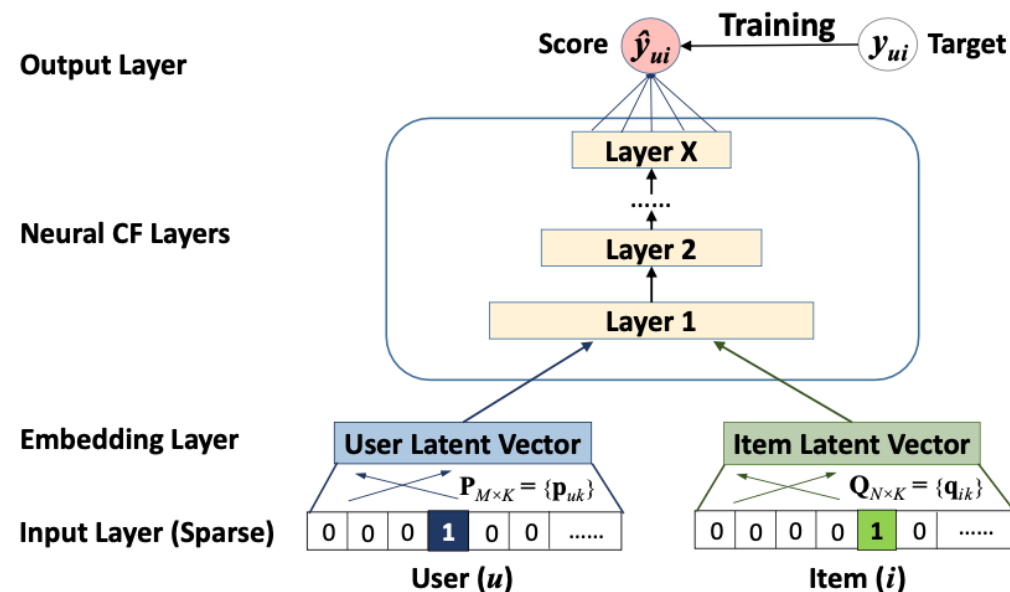

$$\text{RMSE}(\hat{R}, R) = \text{sqrt} \left( \frac{1}{|E|} \sum_{(x,i) \in E} (\hat{r}_{xi} - r_{xi})^2 \right)$$

- $E$  is the set of non-blank entries.

$$\text{RMSE} \left( \underset{R}{\begin{bmatrix} 5 & 2 \\ 3 & \end{bmatrix}}, \underset{UV^T}{\begin{bmatrix} 2 & 2 \\ 2 & 2 \end{bmatrix}} \right) = \sqrt{\frac{(5-2)^2 + (2-2)^2 + (3-2)^2}{3}} = 1.826$$

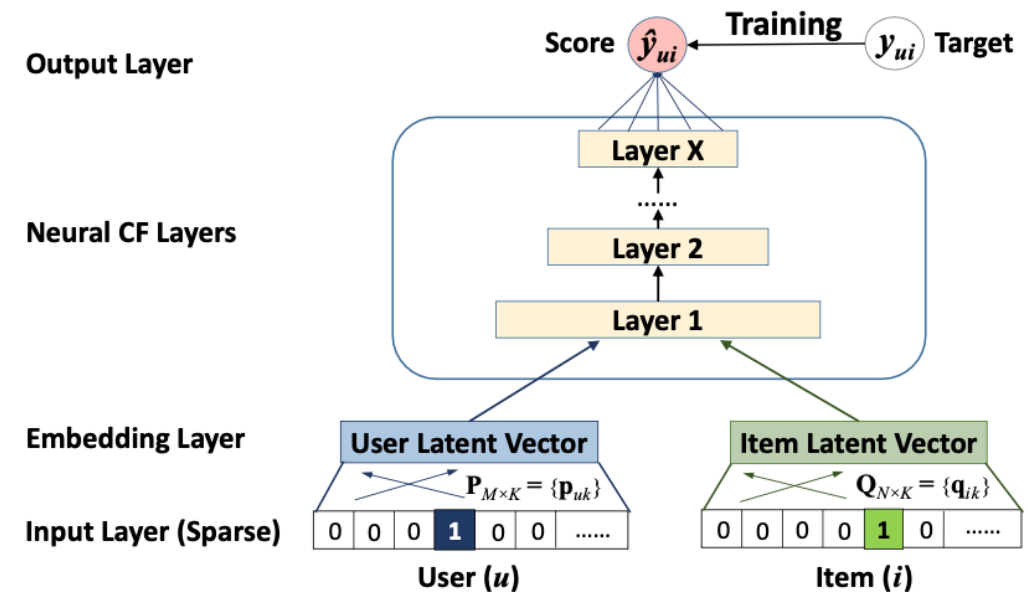

# Neural Collaborative Filtering

- The classical latent factor model is still a **linear** method.
- **Neural collaborative filtering** captures complex interactions.
  - By utilizing the nonlinearity of neural networks.

# Neural Collaborative Filtering

- **Input & embedding layers:**
  - Not different from the latent factor model.
- **Neural CF layers:**
  - Generalizes the (linear) dot product.
  - Take concatenated  $h_u \parallel h_v$  as input.
- **Training:**
  - Can use a proper loss for each data.

# Dealing with Implicit Feedback

- What if the utility matrix  $R$  contains only implicit feedback?
  - Each entry is either 0 (not watched) or 1 (watched).
- Training the model with RMSE loss is not desirable.
  - RMSE assumes 0 as a dislike, not “not watched.”
  - Model will be trained not to recommend all unwatched movies.

# Ranking Loss

- **Idea:** Let's consider the task as **ranking**, not *elementwise prediction*.
  - Given a user  $x$ , suppose that  $r_{xi} = 1$  while  $r_{xj} = 0$ .
  - It's hard to assume that user  $x$  **dislikes** movie  $j$ .
  - But we can safely assume that user  $x$  likes  $i$  **more than**  $j$ .
    - If  $x$  really likes  $j$ , they would have watched it before  $i$ .
  - Let's train the model by comparing items, so that  $u_{xi} > u_{xj}$ .

# Bayesian Personalized Ranking

- We may use the **Bayesian personalized ranking (BPR)** loss:

$$J_{\text{BPR}}(U, V) = \sum_{x, i, j} -\log \sigma(u_x^\top v_i - u_x^\top v_j)$$

- Item  $j$  is randomly selected from the **negative samples**  $\{j \mid r_{xj} = 0\}$ .
- In this way, the model is trained to satisfy  $u_x^\top v_i > u_x^\top v_j$ .
- The **sigmoid function**  $\sigma$  is used to balance the difference.

# Sigmoid Function

- **Sigmoid function**  $\sigma$  limits the output to be  $[0, 1]$ :

$$\sigma(x) = \frac{1}{1 + e^{-x}}$$

- Maps  $(-\infty, \infty)$  to  $(0, 1)$  with  $\sigma(0) = 0.5$ .
- Monotonically increasing for all ranges of  $x$ .

# Outline

1. Introduction
2. Content-based models
3. Collaborative filtering
4. Latent factor models
5. **Summary**

# Summary

- Recommendation is an essential task in data mining.
- Collaborative filtering is one of the most popular approaches.
  - Models the interactions between users and items.
- Deep models improve collaborative filtering via nonlinearity.
- Modern approaches utilize the structure under the given data.
